It was recently shown by computer simulations that a large class of liquids exhibits strong correlations in their thermal fluctuations of virial and potential energy [Pedersen *et al.*, Phys. Rev. Lett. **100**, 015701 (2008)]. Among organic liquids the class of strongly correlating liquids includes van der Waals liquids, but excludes ionic and hydrogen-bonding liquids. The present note focuses on the density scaling of strongly correlating liquids, i.e., the fact their relaxation time  $\tau$  at different densities  $\rho$  and temperatures  $T$  collapses to a master curve according to the expression  $\tau \propto F[\rho^\gamma/T]$  [Schröder *et al.*, arXiv:0803.2199]. We here show how to calculate the exponent  $\gamma$  from bulk modulus and specific heat data, either measured as functions of frequency in the metastable liquid or extrapolated from the glass and liquid phases to a common temperature (close to the glass transition temperature). Thus an exponent defined from the response to highly nonlinear parameter changes may be determined from linear response measurements.

## Introduction

A liquid is termed “strongly correlating” if its virial ( $W$ ) and potential energy ( $U$ ) equilibrium fluctuations correlate better than 90% [2, 3, 10] at constant volume and temperature,

$$\Delta W(t) \cong \gamma \Delta U(t). \quad (1)$$

where  $\Delta W(t) = W(t) - \langle W \rangle$ ,  $\Delta U(t) = U(t) - \langle U \rangle$ . The “slope” is defined as

$$\gamma \equiv \sqrt{\frac{\langle (\Delta W)^2 \rangle}{\langle (\Delta U)^2 \rangle}} \quad (2)$$

and the correlation coefficient is defined as

$$R \equiv \frac{\langle \Delta W \Delta U \rangle}{\sqrt{\langle (\Delta W)^2 \rangle \langle (\Delta U)^2 \rangle}}. \quad (3)$$

We have previously shown that the fluctuations of such liquids are well described by those generated by soft-sphere potentials (inverse power law potentials) [2, 3]. Strongly correlating liquids are approximate single-parameter liquids [1, 6, 11]. Moreover the density scaling exponent is one third of the exponent of the approximate inverse power law potentials [5, 14]. Recall that density (thermodynamic) scaling applies whenever the relaxation time  $\tau$  at different densities  $\rho$  and temperatures  $T$  collapse to a master curve according to the expression  $\tau \propto F[\rho^\gamma/T]$ . It is generally reported now that density scaling applies for van der Waals liquids, but e.g. not for hydrogen-bonding liquids. This is consistent with our finding that the class of strongly correlating liquids includes van der Waals and metallic liquids, but excludes covalent, ionic, or hydrogen-bonding liquids – the latter three classes of liquids have competing interactions that spoil the  $WU$  correlation [2, 3, 10].

## Fluctuation expressions

Consider a viscous liquid with slow structural relaxation, i.e., with a relaxation time  $\tau$  that is much larger than one picosecond. The fluctuation-dissipation (FD) theorem for the frequency-dependent specific heat per unit volume,  $c_V(\omega)$ , is given [9] by

$$k_B T^2 V c_V(\omega) = \langle (\Delta E)^2 \rangle - i\omega \int_0^\infty \langle \Delta E(0) \Delta E(t) \rangle e^{-i\omega t} dt. \quad (4)$$

Relaxation takes place over a limited range of frequencies – typically 3-5 decades. By subtracting the responses at high (“ $\infty$ ”) and low (“0”) frequencies well outside the relaxation frequency range, it follows that if  $t_s$  is a time much shorter than those of the relaxations, but much longer than one picosecond, then

$$k_B T^2 V (c_V(0) - c_V(\infty)) = \langle \Delta E(0) \Delta E(t_s) \rangle. \quad (5)$$

Write the energy as potential plus kinetic energy,  $E = U + K$ . Because the kinetic energy in the NVT ensemble fluctuates fast compared to  $t_s$  one has  $\langle \Delta E(0) \Delta E(t_s) \rangle \cong \langle \Delta U(0) \Delta U(t_s) \rangle$ . Thus,

$$k_B T^2 V (c_V(0) - c_V(\infty)) = \langle (\Delta U)^2 \rangle^{\text{slow}} \quad (6)$$

where  $\langle (\Delta U)^2 \rangle^{\text{slow}} = \langle \Delta U(0) \Delta U(t_s) \rangle$  is the slow part of the potential energy fluctuations, i.e., slow compared to the picosecond time scale.

Since the low-frequency limit gives the ordinary (dc) liquid specific heat and the high-frequency limit gives the “glassy” specific heat corresponding to perturbations that probe a frozen structure, this result may be written

$$\langle (\Delta U)^2 \rangle^{\text{slow}} = k_B T^2 V (c_V^{\text{liquid}} - c_V^{\text{solid}}). \quad (7)$$

Similarly one finds for the virial fluctuations (where  $K_T$  is the isothermal bulk modulus)

$$\langle (\Delta W)^2 \rangle^{\text{slow}} = -k_B T V (K_T^{\text{liquid}} - K_T^{\text{solid}}) \quad (8)$$

and for the virial / potential energy correlation (where  $\beta$  is the pressure coefficient)

$$\langle \Delta W \Delta U \rangle^{\text{slow}} = k_B T^2 V (\beta_V^{\text{liquid}} - \beta_V^{\text{solid}}). \quad (9)$$

#### Calculating $R$ and $\gamma$ from data

The  $WU$  correlation coefficient (Eq. 3) on the  $t_s$  timescale can now be expressed in terms of experimental linear response quantities as follows:

$$R = \frac{(\beta_V^{\text{liquid}} - \beta_V^{\text{solid}})}{\sqrt{-(K_T^{\text{liquid}} - K_T^{\text{solid}})(c_V^{\text{liquid}} - c_V^{\text{solid}})/T}}. \quad (10)$$

Similarly the slope (Eq. 2) can be calculated as

$$\gamma = \sqrt{\frac{-(K_T^{\text{liquid}} - K_T^{\text{solid}})}{T(c_V^{\text{liquid}} - c_V^{\text{solid}})}}. \quad (11)$$

#### Calculating $\gamma$ for the commercial silicone oil DC704

The slope  $\gamma$  may be estimated from the high- and low-frequency limits of  $c_p(\omega)$  and  $K_S(\omega)$  (and a rough estimate of  $\alpha_p$ ) by proceeding as follows. Recall the identities

$$c_V = c_p - T \alpha_p^2 K_T \quad (12)$$

and

$$K_T = K_S \frac{c_V}{c_p}. \quad (13)$$

Combining these we get

TABLE I:  $\gamma$  of DC704 data of from the high and low frequency limit of  $c_p(\omega)$  and  $K_S(\omega)$  [7]. <sup>a</sup>  $\alpha_p^{\text{solid}}$  is estimated as a typical value of solids.

$T$ [K]	214
$c_p^{\text{liquid}}$ [ $10^6$ J/(K m <sup>3</sup> )]	1.40
$c_p^{\text{solid}}$ [ $10^6$ J/(K m <sup>3</sup> )]	1.05
$K_S^{\text{liquid}}$ [ $10^9$ Pa]	3.6
$K_S^{\text{solid}}$ [ $10^9$ Pa]	5.1
$\alpha_p^{\text{liquid}}$ [ $10^{-3}$ K <sup>-1</sup> ]	0.5
$\alpha_p^{\text{solid}}$ [ $10^{-3}$ K <sup>-1</sup> ]	0.1 <sup>a</sup>
$T(\alpha_p^{\text{liquid}})^2 K_S^{\text{liquid}} / c_p^{\text{liquid}}$	0.13
$T(\alpha_p^{\text{solid}})^2 K_S^{\text{solid}} / c_p^{\text{solid}}$	0.01
$c_V^{\text{liquid}}$ [ $10^6$ J/(K m <sup>3</sup> )]	1.24
$c_V^{\text{solid}}$ [ $10^6$ J/(K m <sup>3</sup> )]	1.04
$K_T^{\text{liquid}}$ [ $10^9$ Pa]	3.1
$K_T^{\text{solid}}$ [ $10^9$ Pa]	5.0
$\gamma$ (Eq. 11)	6

$$c_V = c_p \left( 1 + \frac{T \alpha_p^2 K_S}{c_p} \right)^{-1}, \quad (14)$$

and

$$K_T = K_S \left( 1 + \frac{T \alpha_p^2 K_S}{c_p} \right)^{-1}. \quad (15)$$

The value  $\gamma = 6$  is calculated from these expressions using our unpublished linear response data (table I). Unfortunately no experimental density scaling  $\gamma$ 's are available for this liquid to compare to.

### OTP/OPP mixture and pure OTP

The high- and low-frequency limits of the dynamic response can be estimated by extrapolation of static response functions of the glass and liquid phases to a temperature close to the glass transition temperature  $T_g$ . Table II lists extrapolated values of  $\kappa_T$ ,  $c_p$  and  $\alpha_p$  for a mixture of o-terphenyl (OTP) and o-phenylphenol (OPP), Table III lists values for pure OTP.

From the natural response functions of the constant  $pT$  ensemble it is straightforward to calculate the natural response functions of the constant  $VT$  ensemble:

$$K_T = 1/\kappa_T, \quad (16)$$

$$c_V = c_p - T \alpha_p^2 K_T, \quad (17)$$

and

$$\beta_V = \alpha_p K_T. \quad (18)$$

Using these equations we arrive at the numbers in tables II and III.

TABLE II:  $\gamma$  and  $R$  of OTP-OPP calculated from data on Figure 4 of Ref. [15]

$T_g$ [K]	233.7
$V_g$ [ $10^{-6}$ m <sup>3</sup> /mol]	203.9
$C_p^{\text{liquid}}$ [J/(K mol)]	364
$C_p^{\text{solid}}$ [J/(K mol)]	236
$\kappa_T^{\text{liquid}}$ [ $10^{-9}$ Pa <sup>-1</sup> ]	0.35
$\kappa_T^{\text{solid}}$ [ $10^{-9}$ Pa <sup>-1</sup> ]	0.19
$\alpha_p^{\text{liquid}}$ [ $10^{-3}$ K <sup>-1</sup> ]	0.74
$\alpha_p^{\text{solid}}$ [ $10^{-3}$ K <sup>-1</sup> ]	0.17
$C_V^{\text{liquid}}$ [J/(K mol)]	284
$C_V^{\text{solid}}$ [J/(K mol)]	229
$K_T^{\text{liquid}}$ [ $10^9$ Pa]	2.9
$K_T^{\text{solid}}$ [ $10^9$ Pa]	5.2
$\beta_V^{\text{liquid}}$ [ $10^6$ Pa/K]	2.1
$\beta_V^{\text{solid}}$ [ $10^6$ Pa/K]	0.9
$R$ (Eq. 10)	0.8
$\gamma$ (Eq. 11)	6.0
$\gamma^{\text{scale}}$ (Ref. [13])	6.2

TABLE III:  $\gamma$  and  $R$  for OTP.  $C_p$  values are from Ref. [4].  $K_T = \beta_V/\alpha_p$  is calculated from  $\alpha_p$  and  $\beta_V$  values from Ref. [8].

$T_g$ [K]	244.5
$V_g$ [ $10^{-6}$ m <sup>3</sup> /mol]	206.1
$C_p^{\text{liquid}}$ [J/(K mol)]	336
$C_p^{\text{solid}}$ [J/(K mol)]	228
$\alpha_p^{\text{liquid}}$ [ $10^{-3}$ K <sup>-1</sup> ]	0.71
$\alpha_p^{\text{solid}}$ [ $10^{-3}$ K <sup>-1</sup> ]	0.32
$\beta_V^{\text{liquid}}$ [ $10^6$ Pa/K]	1.56
$\beta_V^{\text{solid}}$ [ $10^6$ Pa/K]	1.16
$C_V^{\text{liquid}}$ [J/(K mol)]	280
$C_V^{\text{solid}}$ [J/(K mol)]	209
$K_T^{\text{liquid}}$ [ $10^9$ Pa]	2.2
$K_T^{\text{solid}}$ [ $10^9$ Pa]	3.6
$R$ (Eq. 10)	0.3
$\gamma$ (Eq. 11)	4.1
$\gamma^{\text{scale}}$ (Ref. [13])	4.0

### Summary

We have shown that it is possible to calculate the density scaling exponent  $\gamma$  from linear response measurements of specific heat and bulk modulus data. There are two ways to do this: Either by measuring broad-range frequency-dependent linear responses in the equilibrium metastable liquid phase or by extrapolations as done when evaluating the Prigogine-Defay ratio [12]. Using the first method for DC704 we find  $\gamma = 6$ . To the best of our knowledge there are yet no density scaling data for this liquid. Using the second method for the OTP-OPP mixture we find  $\gamma = 6.0$  which compares favorably to the density scaling  $\gamma^{\text{scale}} = 6.2$  [13]; similarly we find  $\gamma = 4.1$  for pure OTP that compares favorably to the density scaling  $\gamma^{\text{scale}} = 4.0$  [13]. This good agreement may well be fortuitous given the uncertainties associated with our  $\gamma$  estimates. Nevertheless these preliminary findings suggest that for strongly correlating liquids (“single-parameter liquids”) the density scaling exponent – which refers to highly nonlinear parameter changes – may

be determined from linear response measurements. This is consistent with a general hypothesis of ours that strongly correlating liquids have simpler physics than liquids in general.
